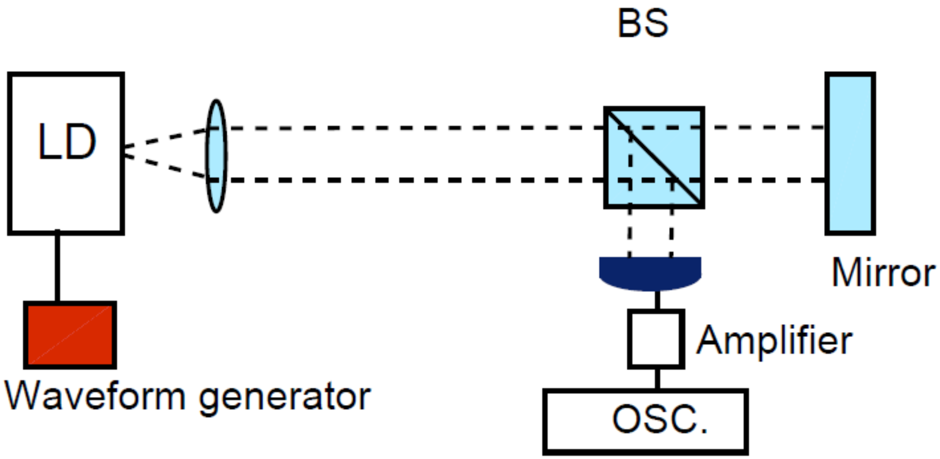
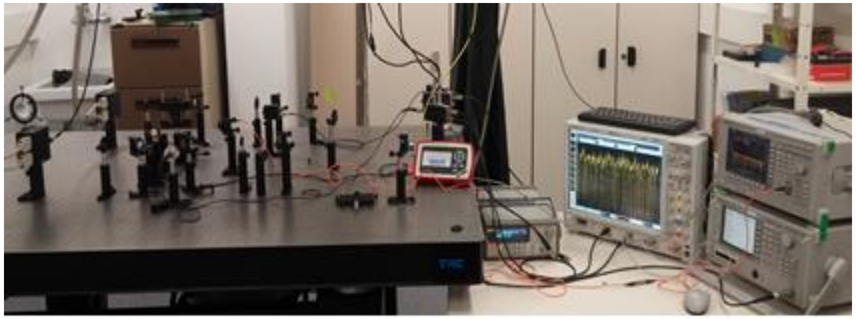
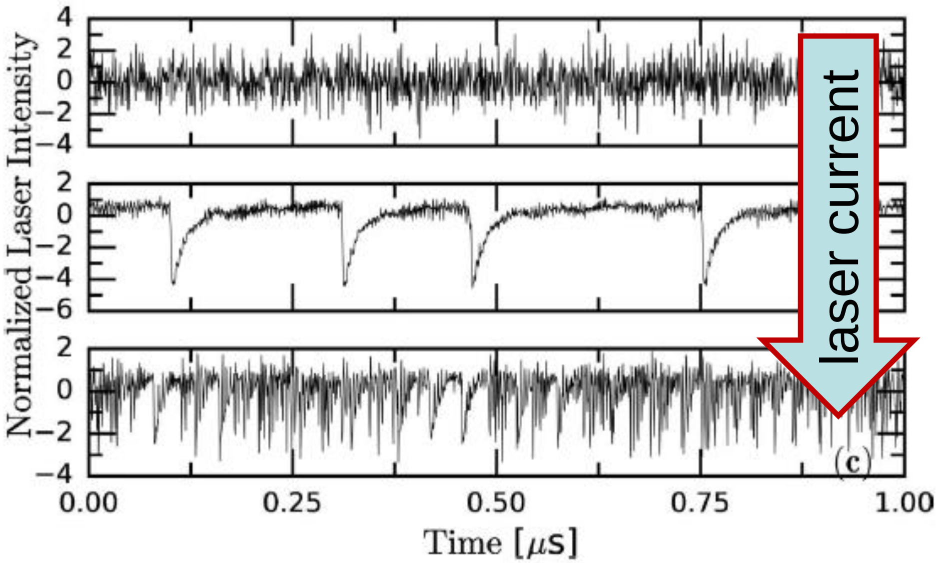
- Characterization of optical spikes
- Control via small electric perturbations

Dynamical transitions in a semiconductor laser with optical feedback

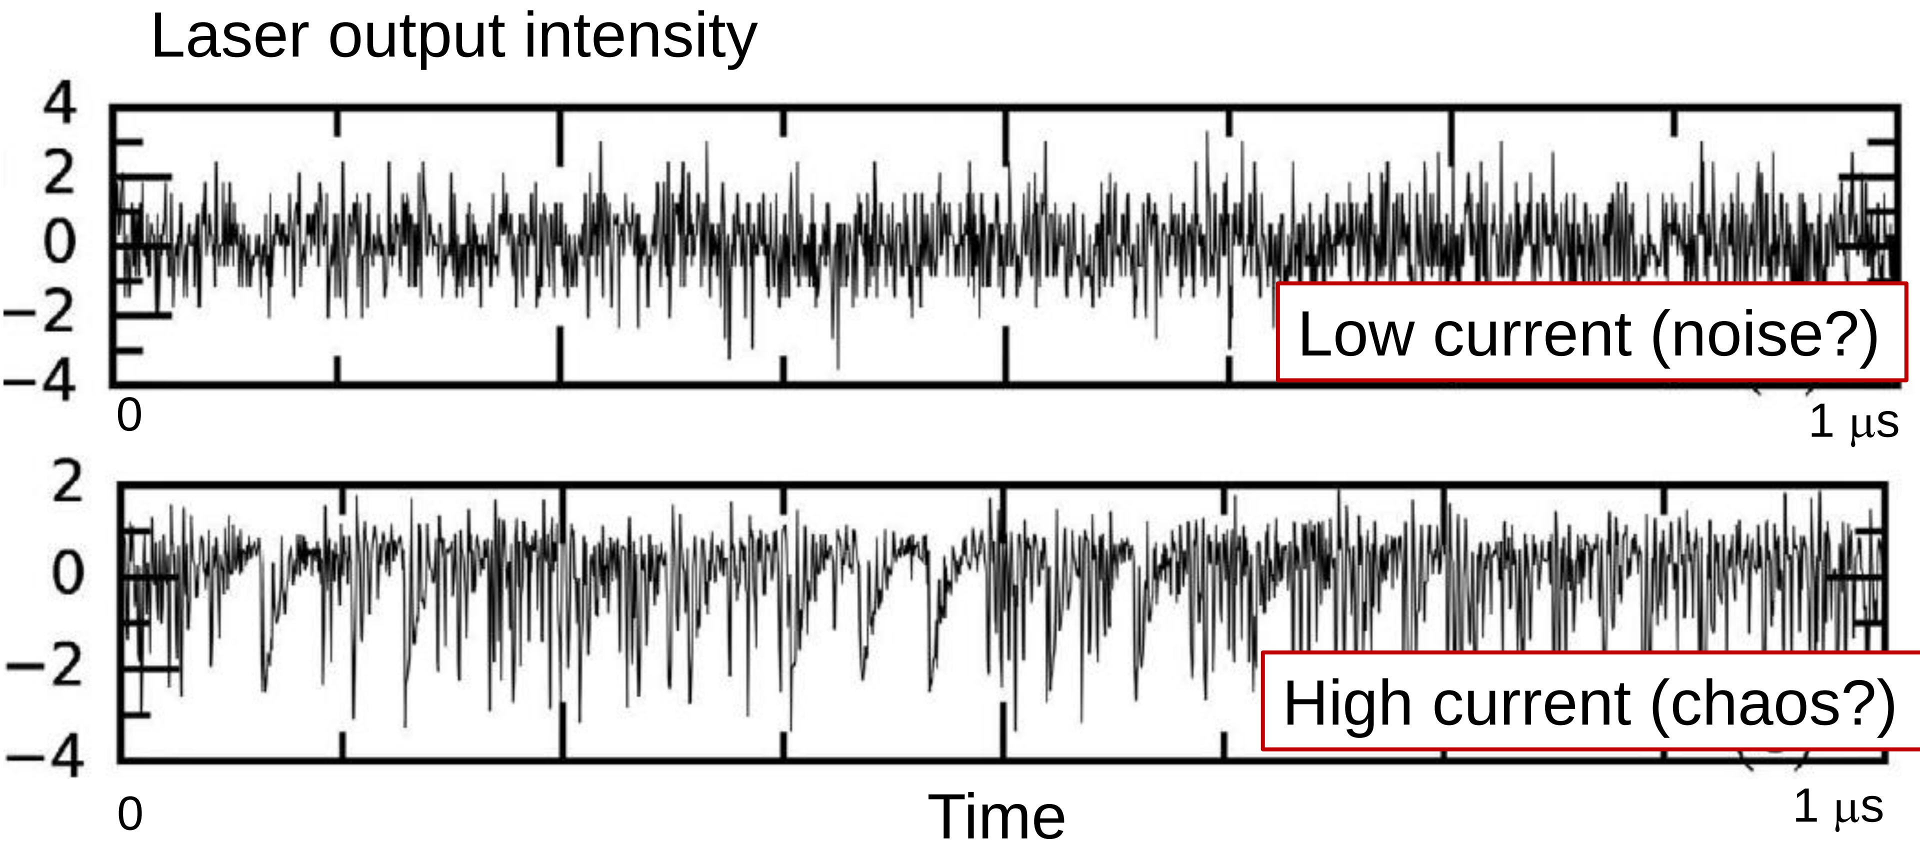






Video: [how complex signals emerge from optical noise]

Different dynamical regimes are difficult to distinguish.



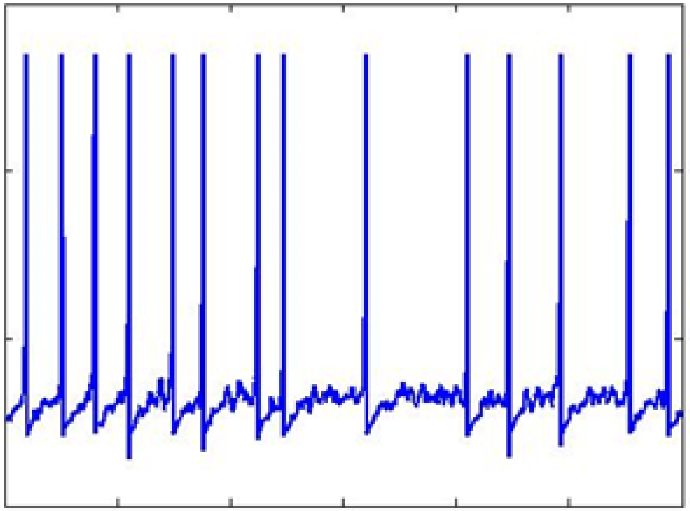
Can differences be quantified? With what reliability?

How similar these time series are?

Optical spikes

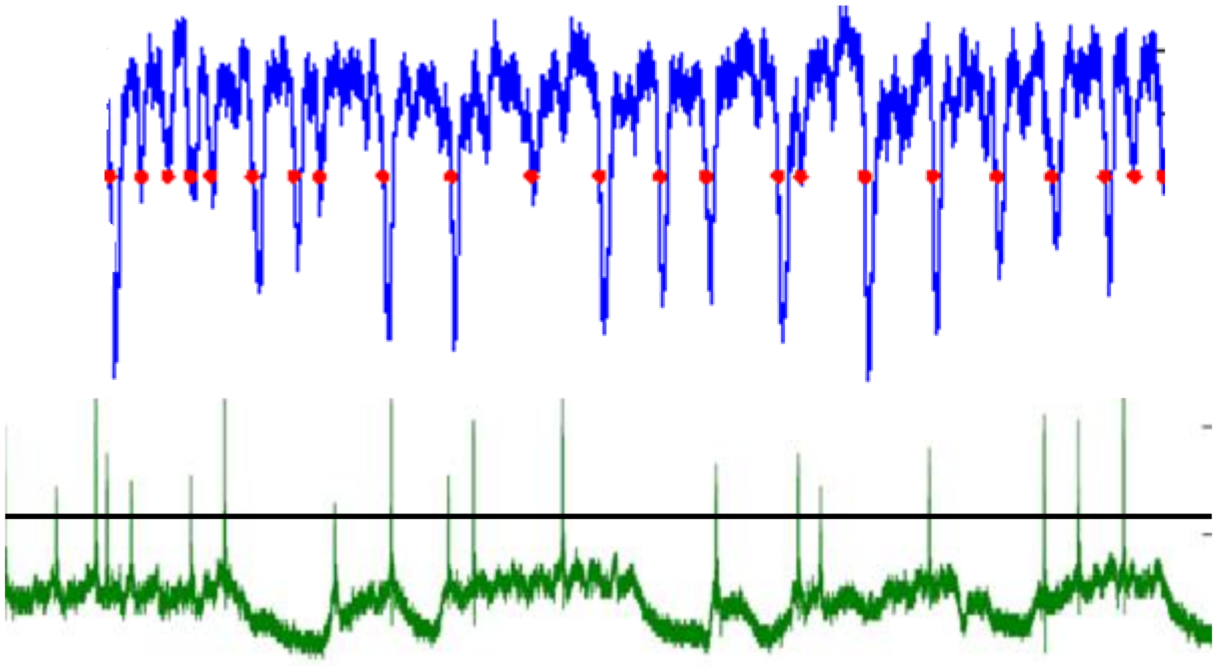
Time

Neuronal spikes



Time

Threshold crossings define ``events'' in a time series

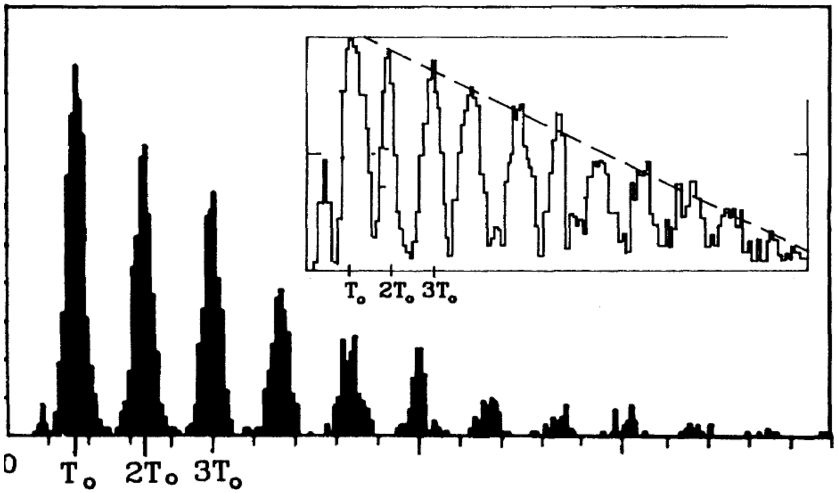


- Problems:
  - How to select the threshold?
  - Threshold dependent results?

inter-spike-intervals (ISIs): $\Delta T_i = t_{i+1} - t_i$

ISI distribution indicates that neurons and lasers have a similar response to external periodic forcing

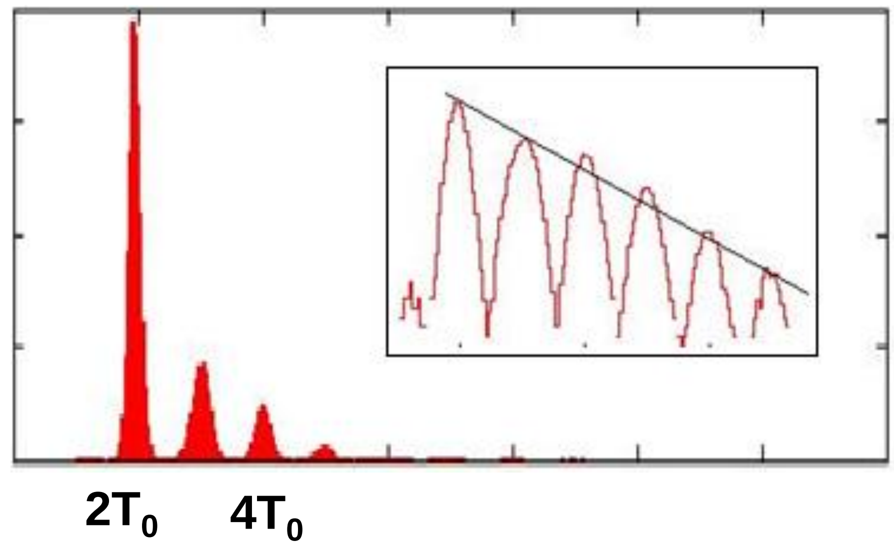
Neuron data



Single auditory nerve fiber of a squirrel monkey with a sinusoidal sound stimulus applied at the ear.

A. Longtin et al PRL (1991)

Laser data



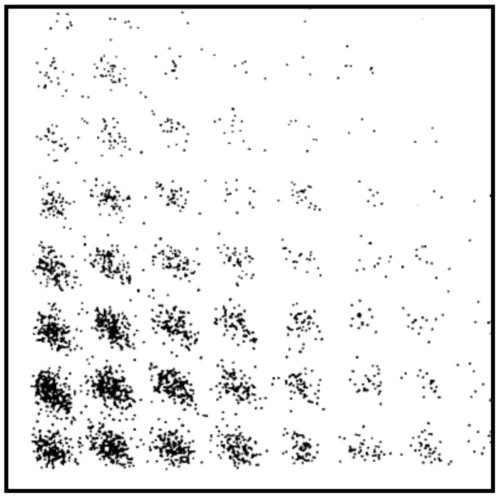
Data recorded in our lab when a sinusoidal signal is applied to the laser current.

A. Aragoneses et al Optics Express (2014)

Return maps also suggest that neurons and lasers have similar response to external periodic forcing

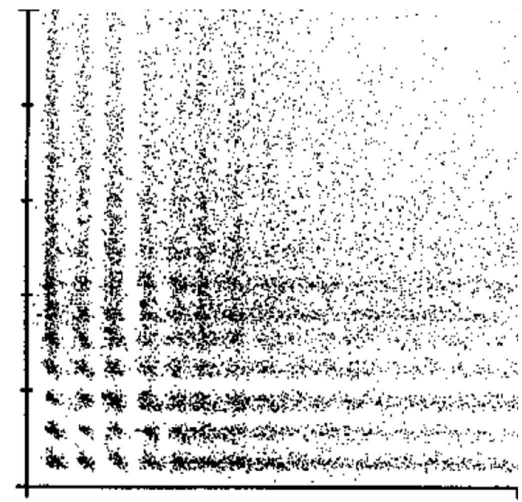
Neuronal ISIs

ΔT_{i+1}



ΔT_i

Laser ISIs



- How to identify temporal order?
- Are there more or less expressed "spike patterns" ?

A. Longtin
Int. J. Bif. Chaos (1993)

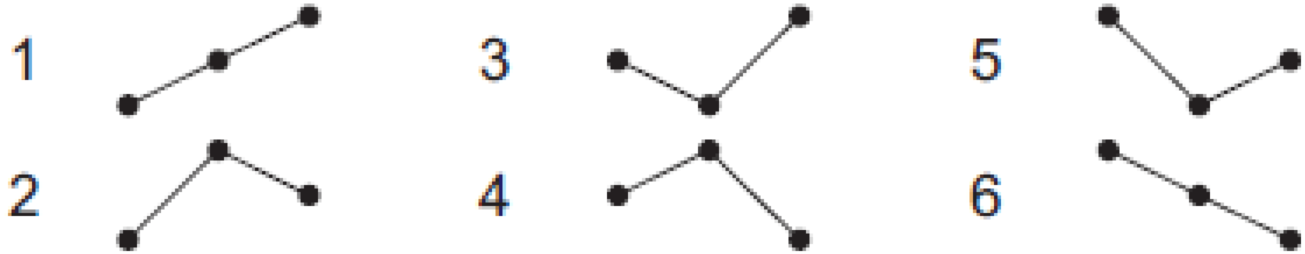
M. Giudici et al PRE (1997)
A. Aragoneses et al
Optics Express (2014)

Different methods of time series analysis provide complementary information

- Many methods
  - Correlation analysis
  - Fourier analysis
  - Lyapunov & fractal analysis
  - Symbolic analysis
  - Wavelet analysis
  - Etc. etc.
- The method to be used depends on the data
  - Length
  - Noise
  - Resolution
  - Etc.

Ordinal analysis: a tool to look for patterns in data

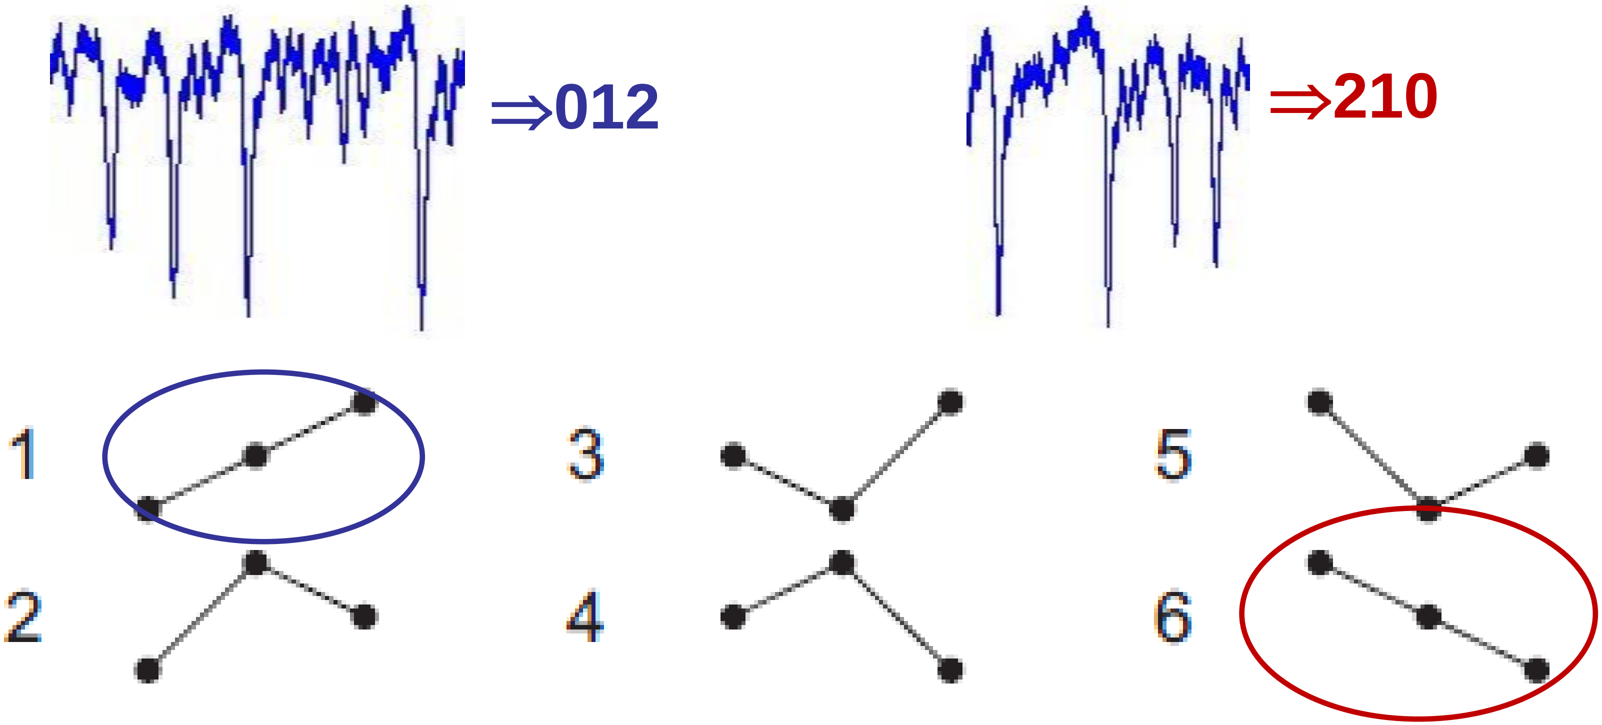
- Consider a time series $x(t)=\{\ldots x_i, x_{i+1}, x_{i+2}, \ldots\}$
- Which are the possible order relations among three data points?



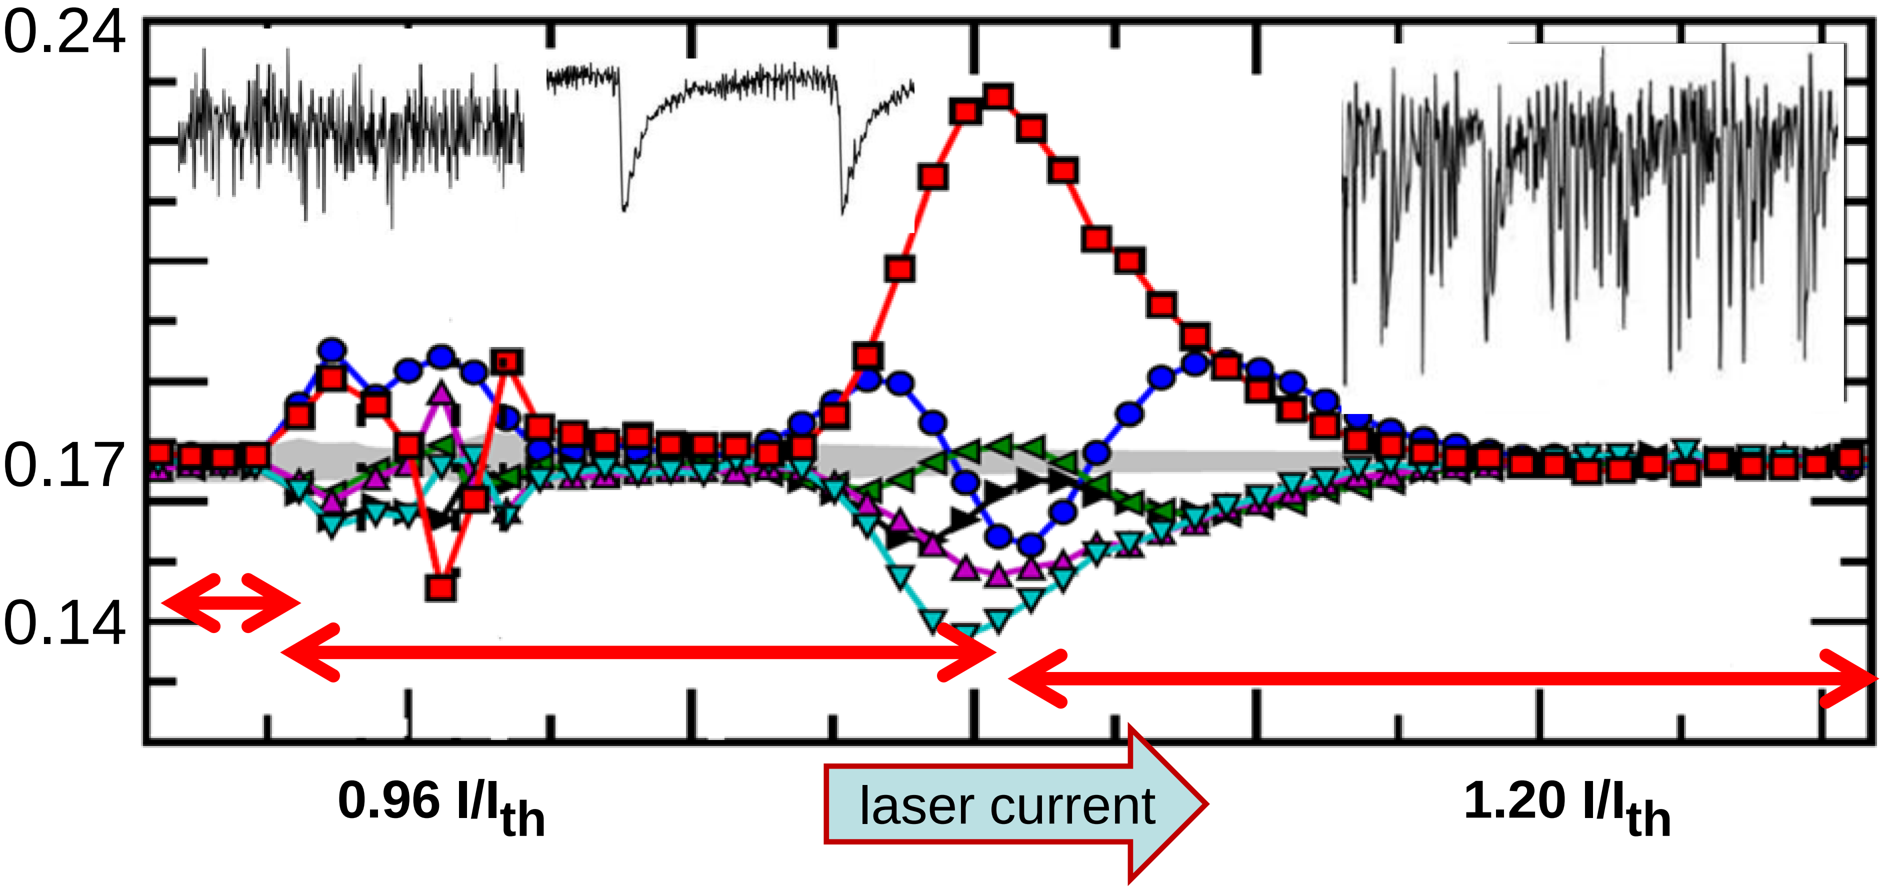
- Count how many times each "ordinal pattern" appears.
- Advantages: allows to identify temporal structures & is robust to noise.
- Drawback: information about actual data values is lost.

Bandt and Pompe PRL (2002)

Ordinal analysis of inter-spike intervals



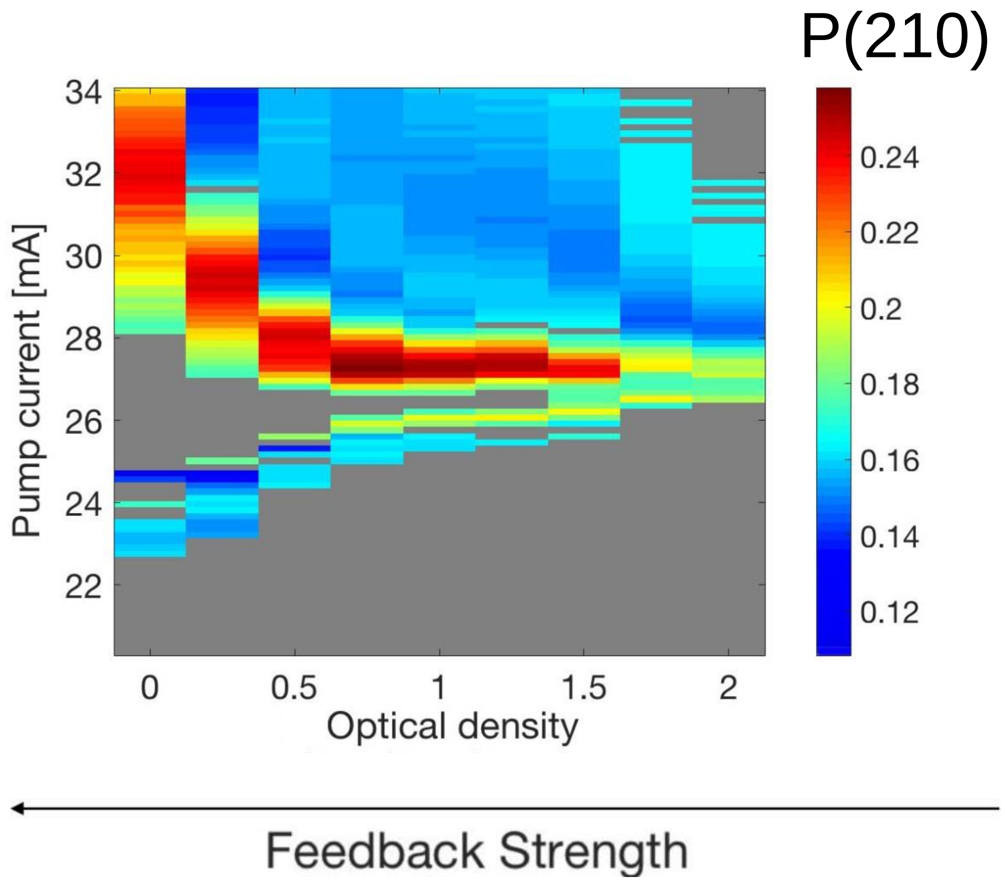
Ordinal analysis identifies the onset of different dynamical regimes, but does not distinguish “noise” and “chaos”



Grey region: probabilities are consistent with the uniform distribution ($P_i = 1/6 \cong 0.17 \ \forall$ i) with 99.7% confidence level

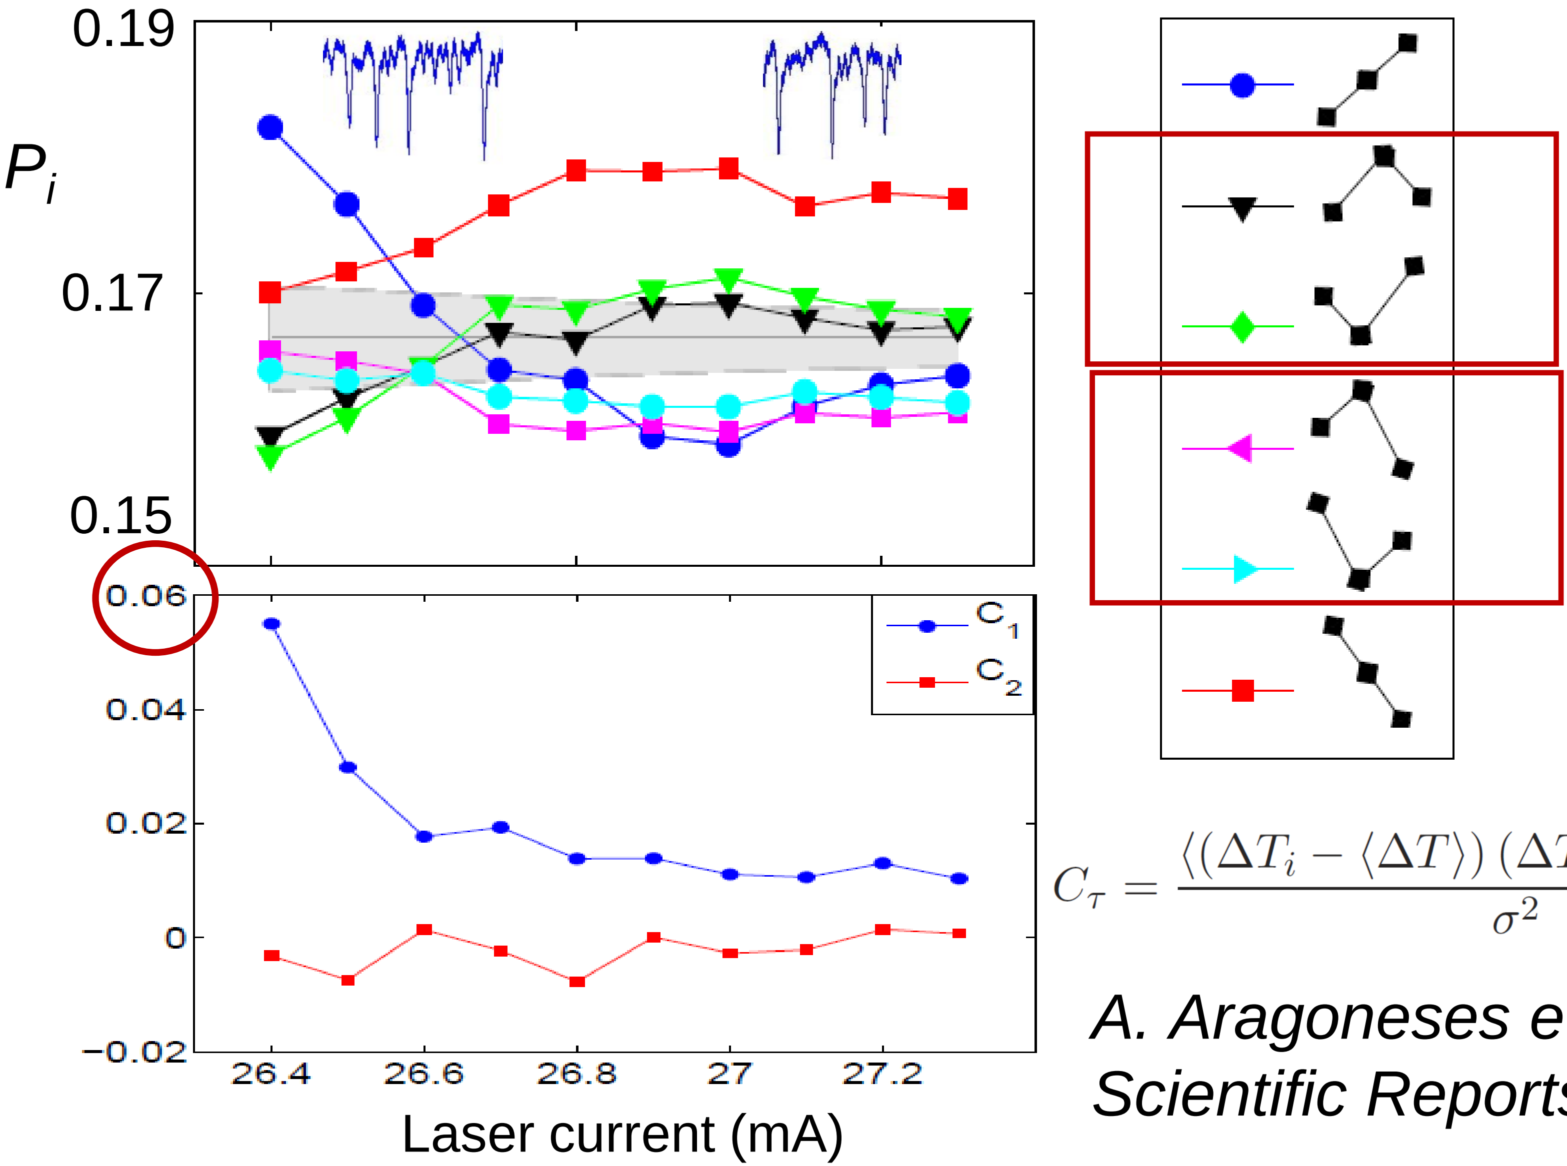
C. Quintero-Quiroz et al, Scientific Reports (2016)

P(210) identifies dynamical regimes in parameter space (pump current, feedback strength)



M. Panozzo et al, Chaos (2017)

Zooming into the region where spikes are well-defined, a transition is detected (not captured by correlation analysis)



$$C_\tau = \frac{\langle (\Delta T_i - \langle \Delta T \rangle)(\Delta T_{i-\tau} - \langle \Delta T \rangle) \rangle}{\sigma^2}$$

A. Aragoneses et al., Scientific Reports (2014)

A modified circle map: simple minimal model

$$\varphi_{i+1} = \varphi_i + \rho + \frac{K}{2\pi}\left[\sin(2\pi\varphi_i) + \alpha_c \sin(4\pi\varphi_i)\right] + D\zeta$$

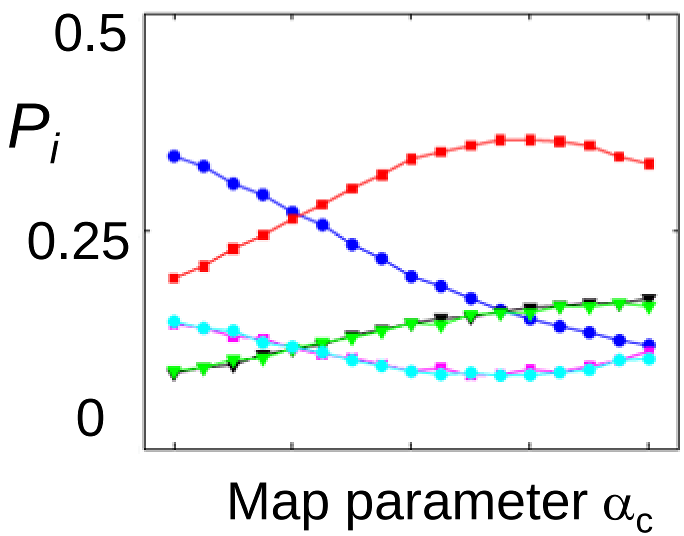
$$X_i = \varphi_{i+1} - \varphi_i$$

$\rho = \dfrac{\text{natural frequency}}{\text{forcing frequency}}$

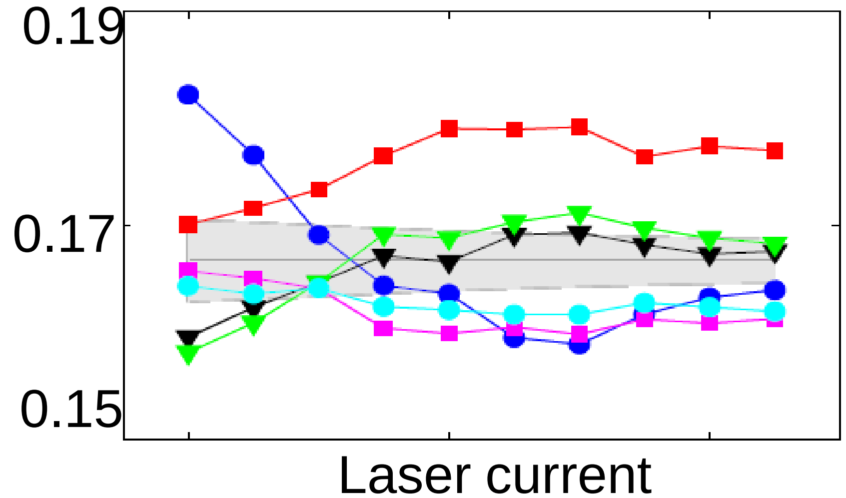
K = forcing amplitude

D = noise strength

Circle map data



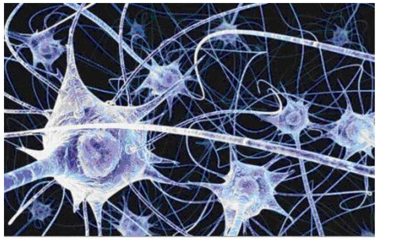
Empirical laser data



Same "clusters" & same hierarchical structure

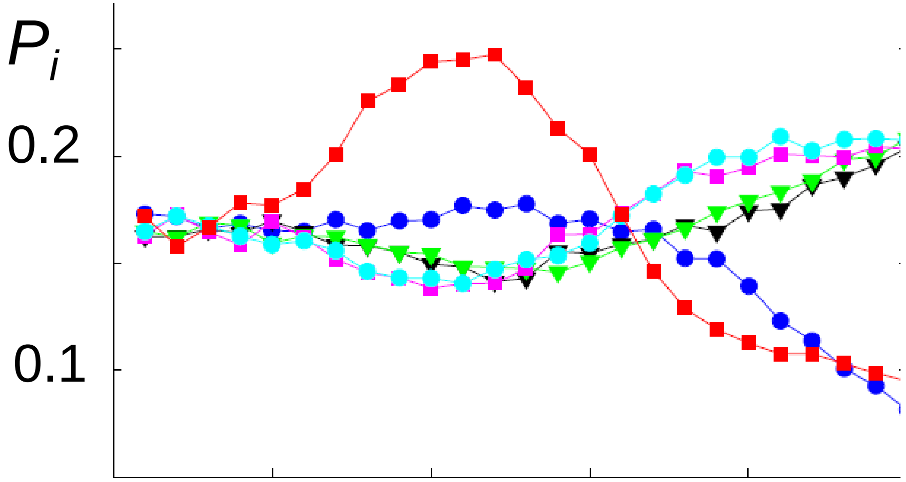
A. Aragoneses et al Scientific Reports (2014)

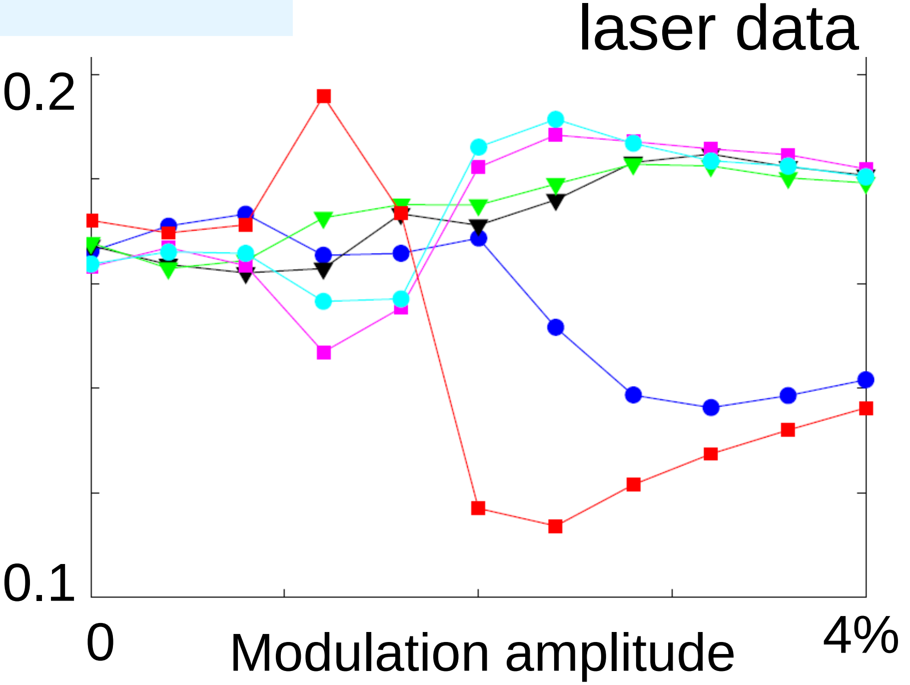
Connection with neurons: the circle map describes many excitable systems



- The modified map describes spike correlations in sensory neurons (Neiman and Russell, PRE 2005)
- Can we test its validity as a minimal model for the laser spikes?

$$\varphi_{i+1} = \varphi_i + \rho + \frac{K}{2\pi}\left[\sin(2\pi\varphi_i) + \alpha_c \sin(4\pi\varphi_i)\right] + D\zeta$$



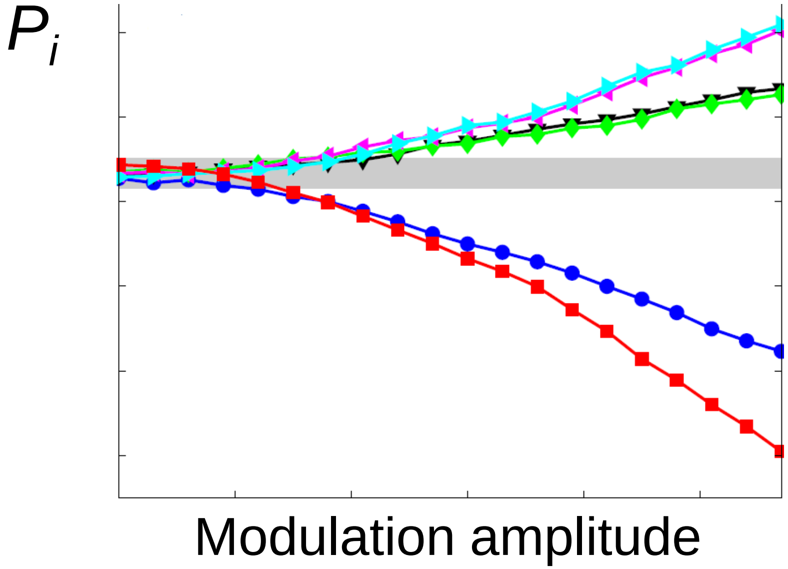


Comparing with synthetic neuronal spikes: good agreement

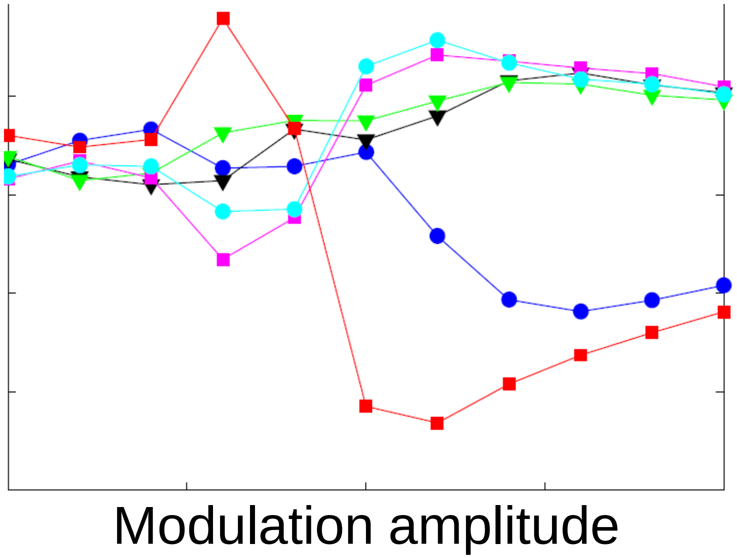
FHN model with Gaussian white noise and **weak** sinusoidal input: spikes are noise-induced

$$\epsilon \frac{dx}{dt} = x - \frac{x^3}{3} - y,$$
$$\frac{dy}{dt} = x + a + \boxed{a_o \cos(2\pi t/T)} + D\xi(t),$$

Synthetic spikes

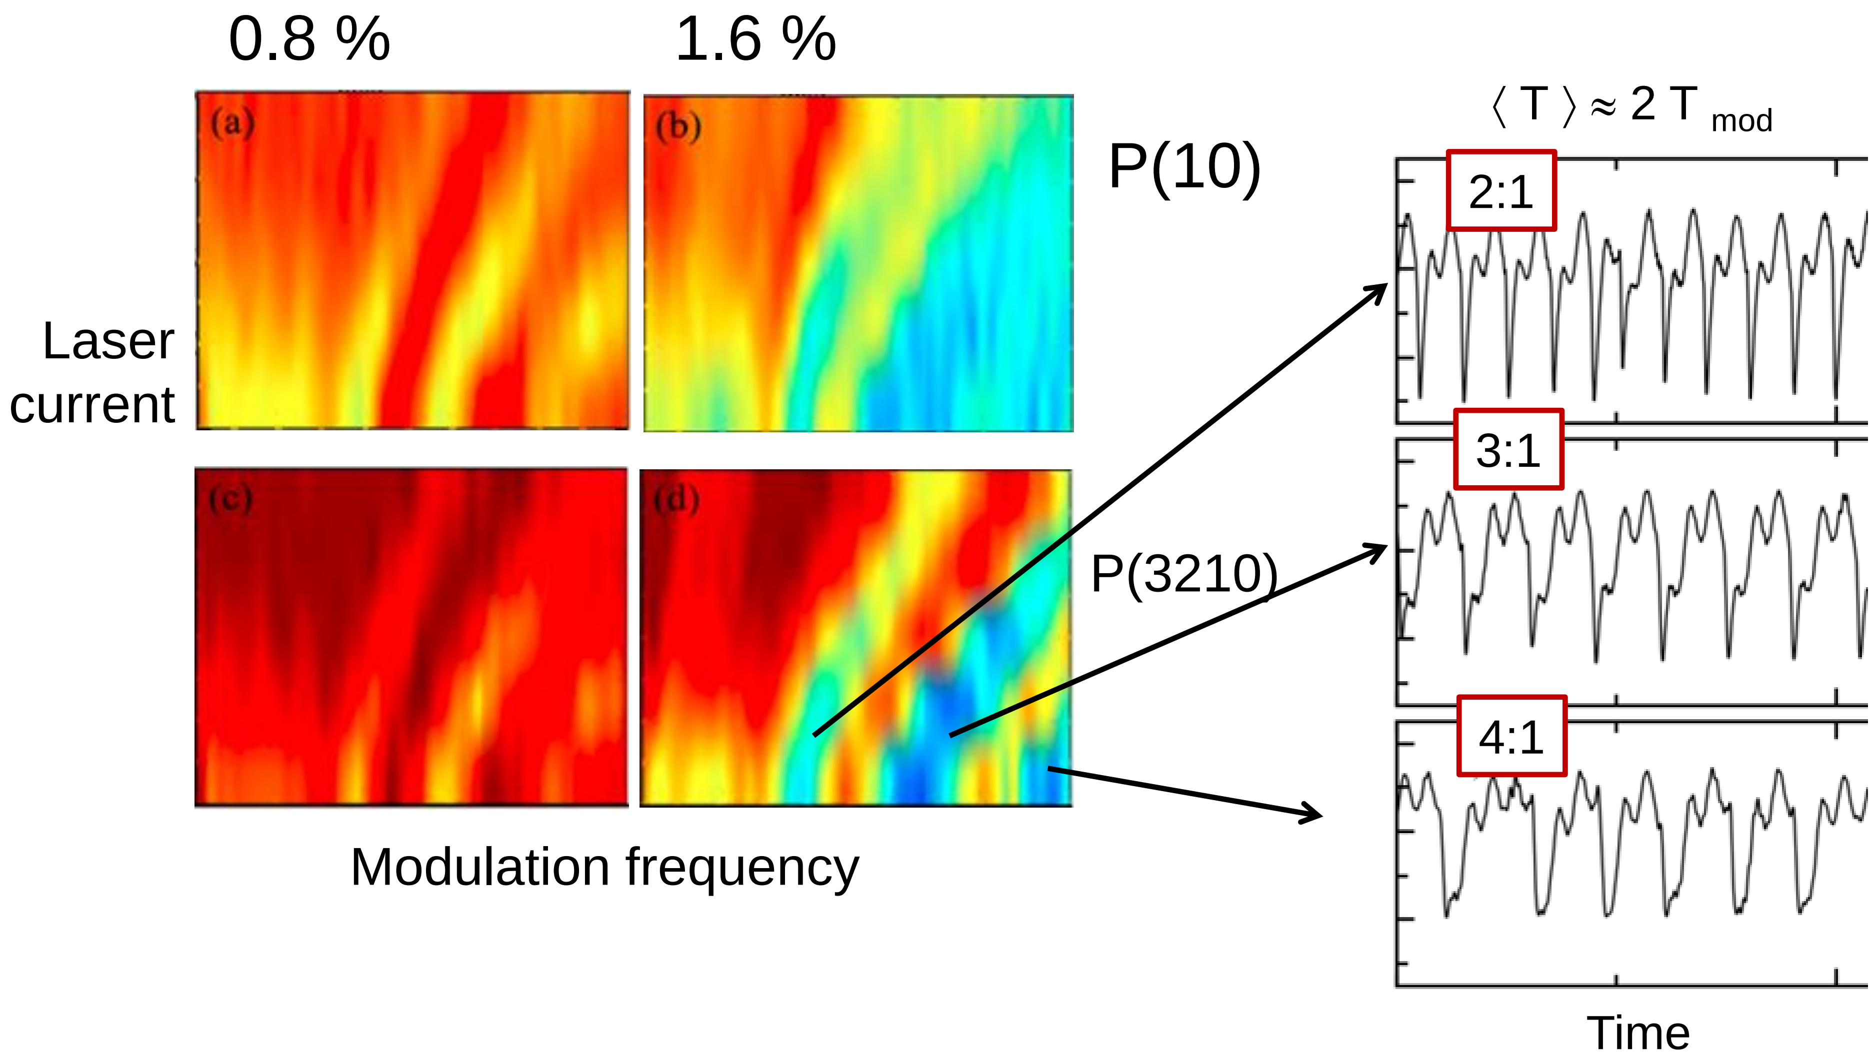


Empirical laser data



Aparicio-Reinoso et al, PRE (2016)

Ordinal probabilities uncover the regions of noisy locking



T. Sorrentino et al, JSTQE (2015)

How to *control* the laser spikes?
How to *quantify* the degree of entrainment?

UNIVERSITAT POLITÈCNICA
DE CATALUNYA
BARCELONATECH

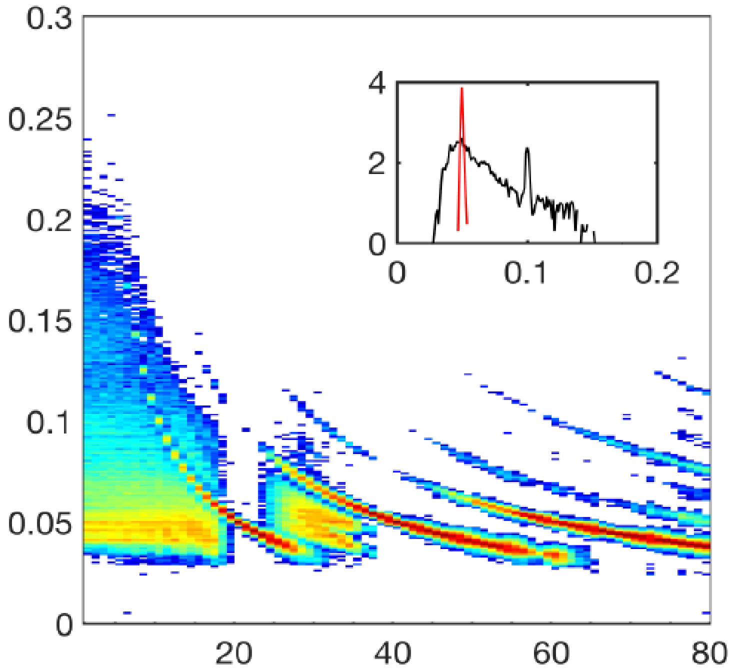
Inter-spike time interval distribution as a function of the frequency of the current modulation

$I_{th,sol} = 26.62$ mA

$I_{th} = 24.70$ mA

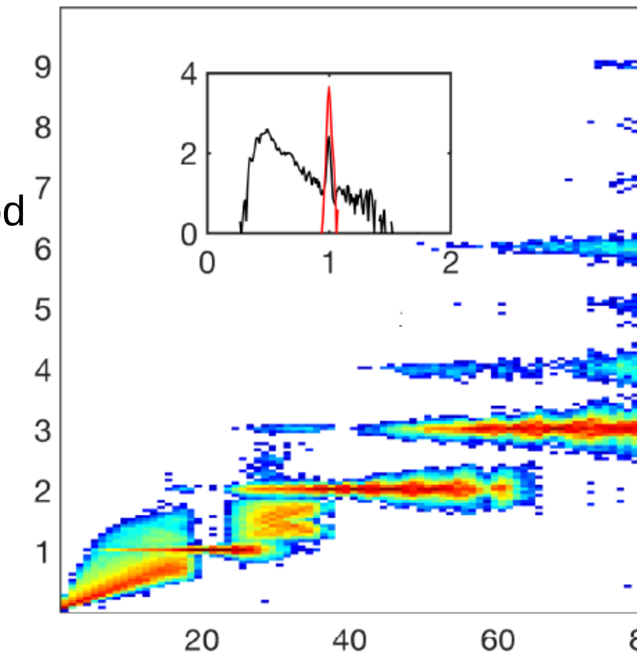
I_{dc}= 27 mA (f_0=15 MHz), A_{mod} = 2.3% of I_{dc}

ISI (µs)



Modulation frequency (MHz)

$\frac{ISI}{T_{mod}}$

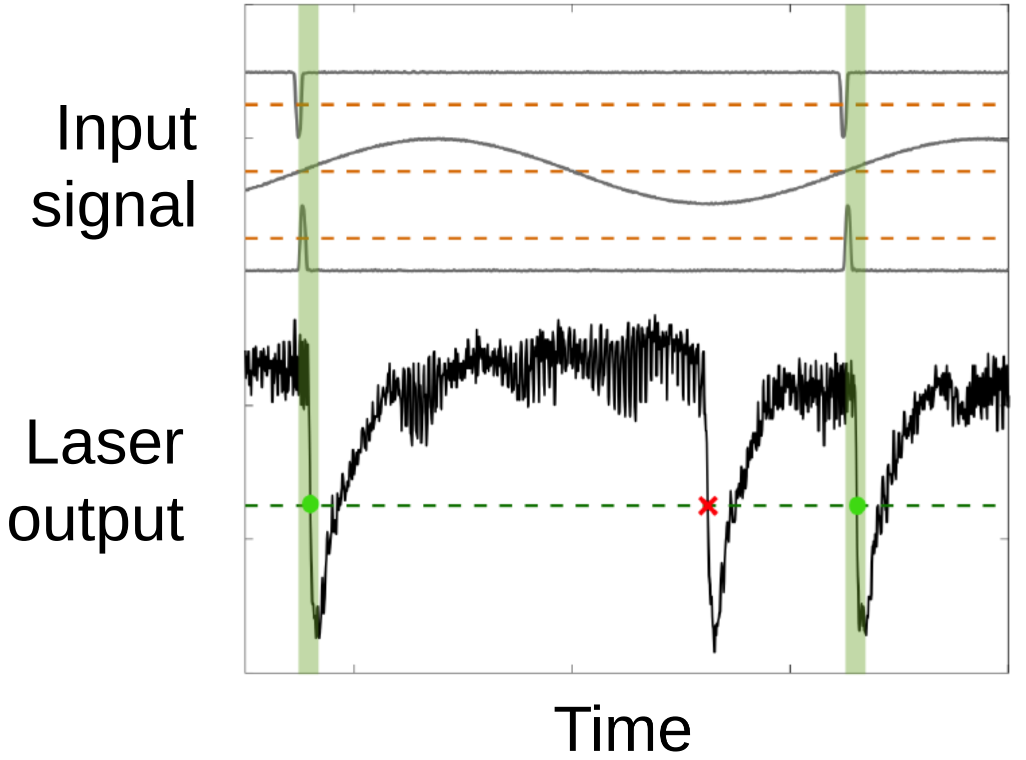


Modulation frequency (MHz)

⇒ “refractory time” clear

⇒ “locking” horizontal

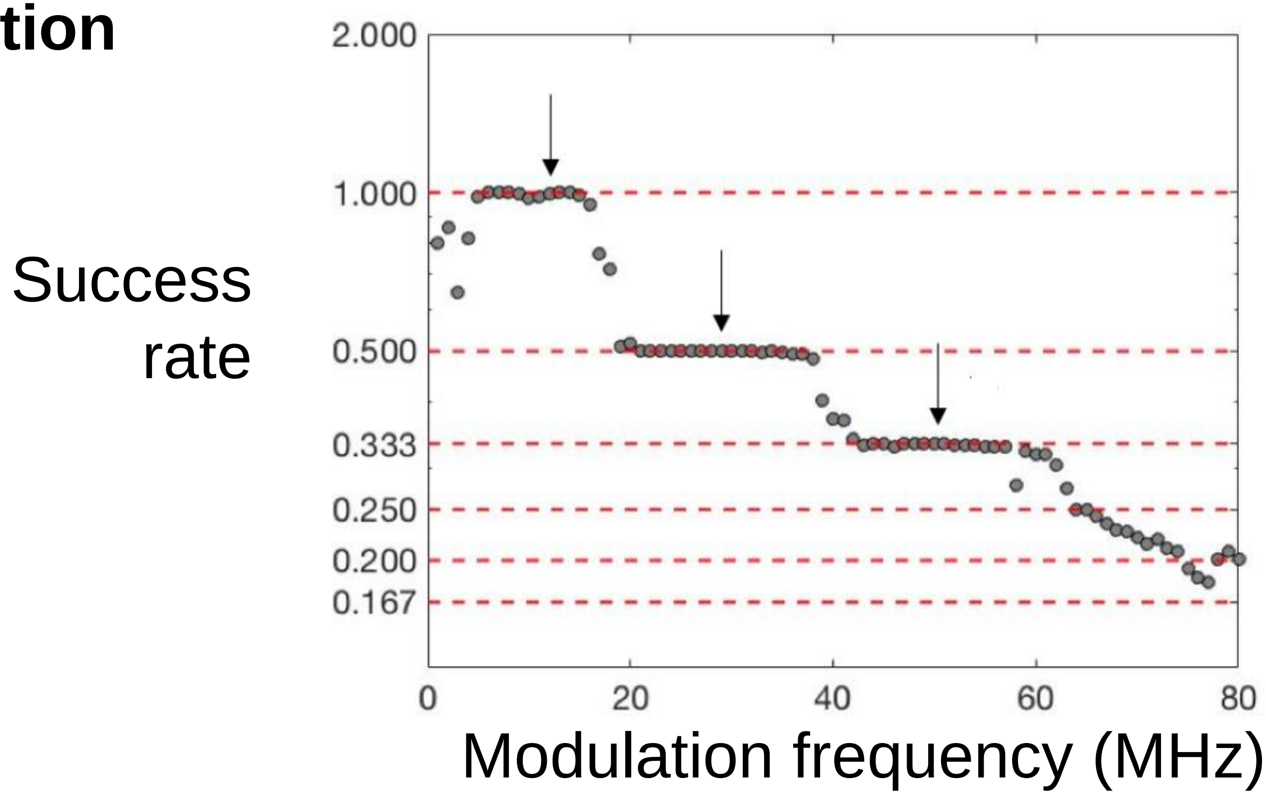
We test three modulation waveforms and quantify locking with the <u>success rate</u> and the <u>false positive rate</u>

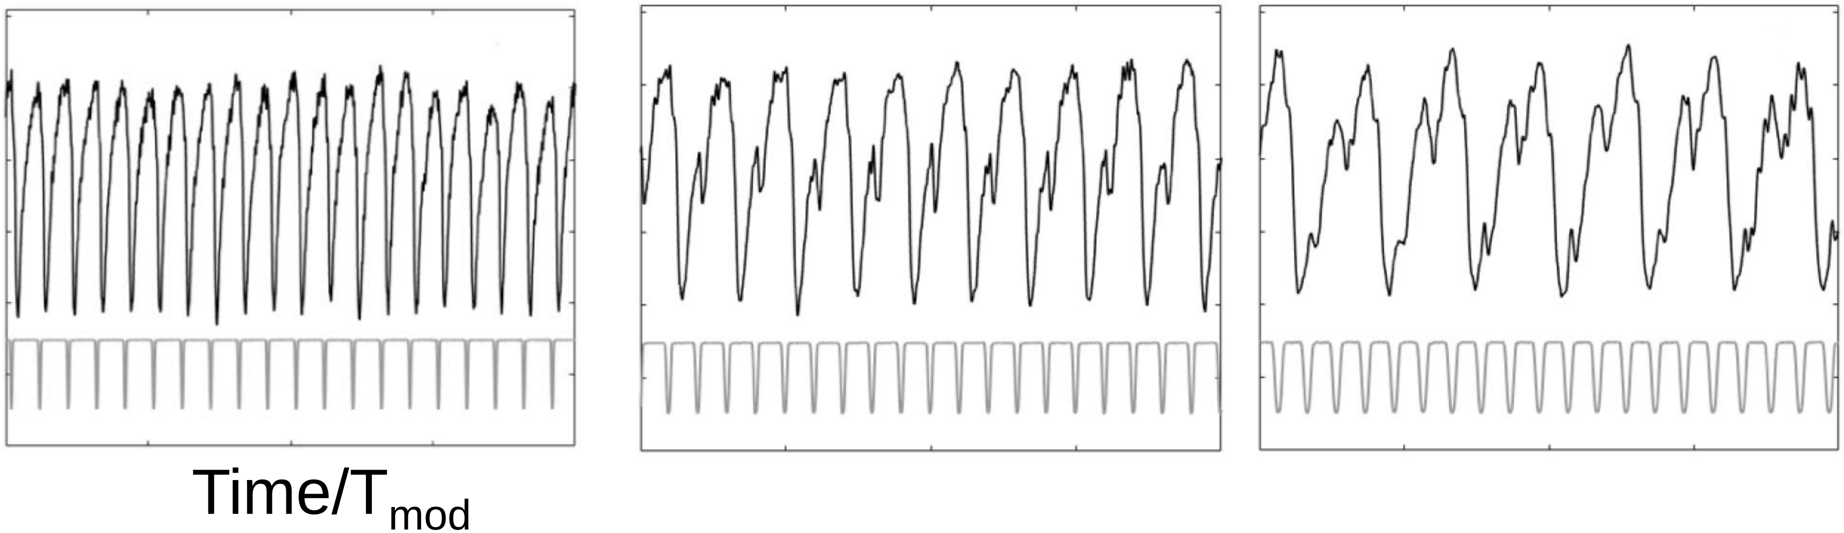


$$\mathrm{SR}(\tau) = \frac{\text{\# of spikes emitted in the interval } \tau}{\text{\# of modulation cycles}}$$

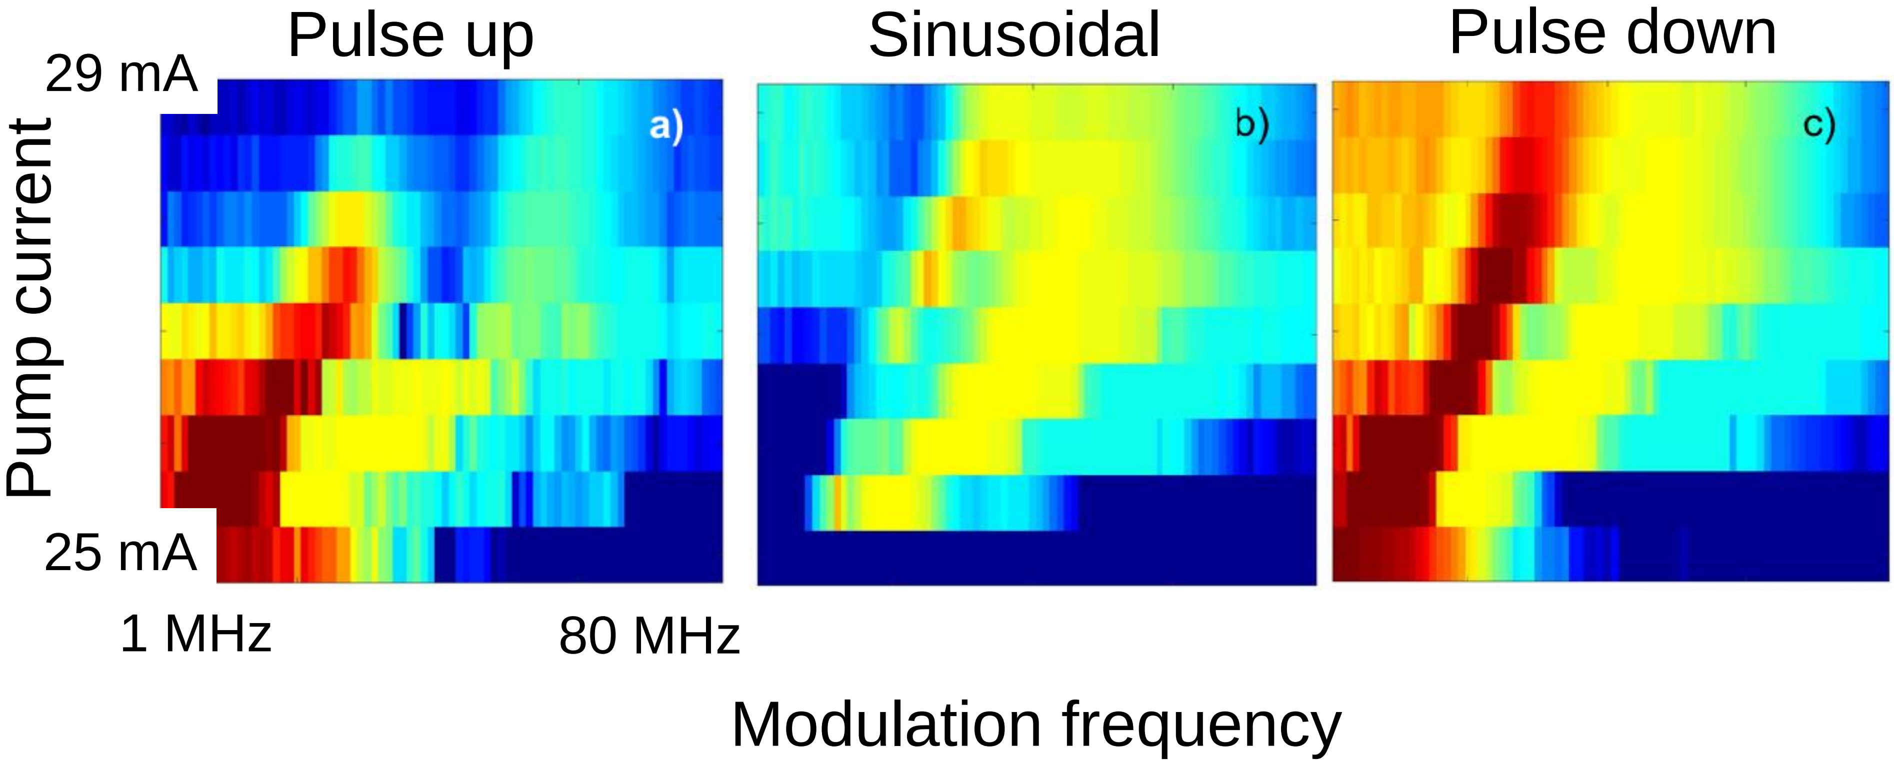
$$\mathrm{FPR}(\tau) = \frac{\text{\# spikes that are not emitted in the time interval } \tau}{\text{Total \# of spikes}}$$

Quantification





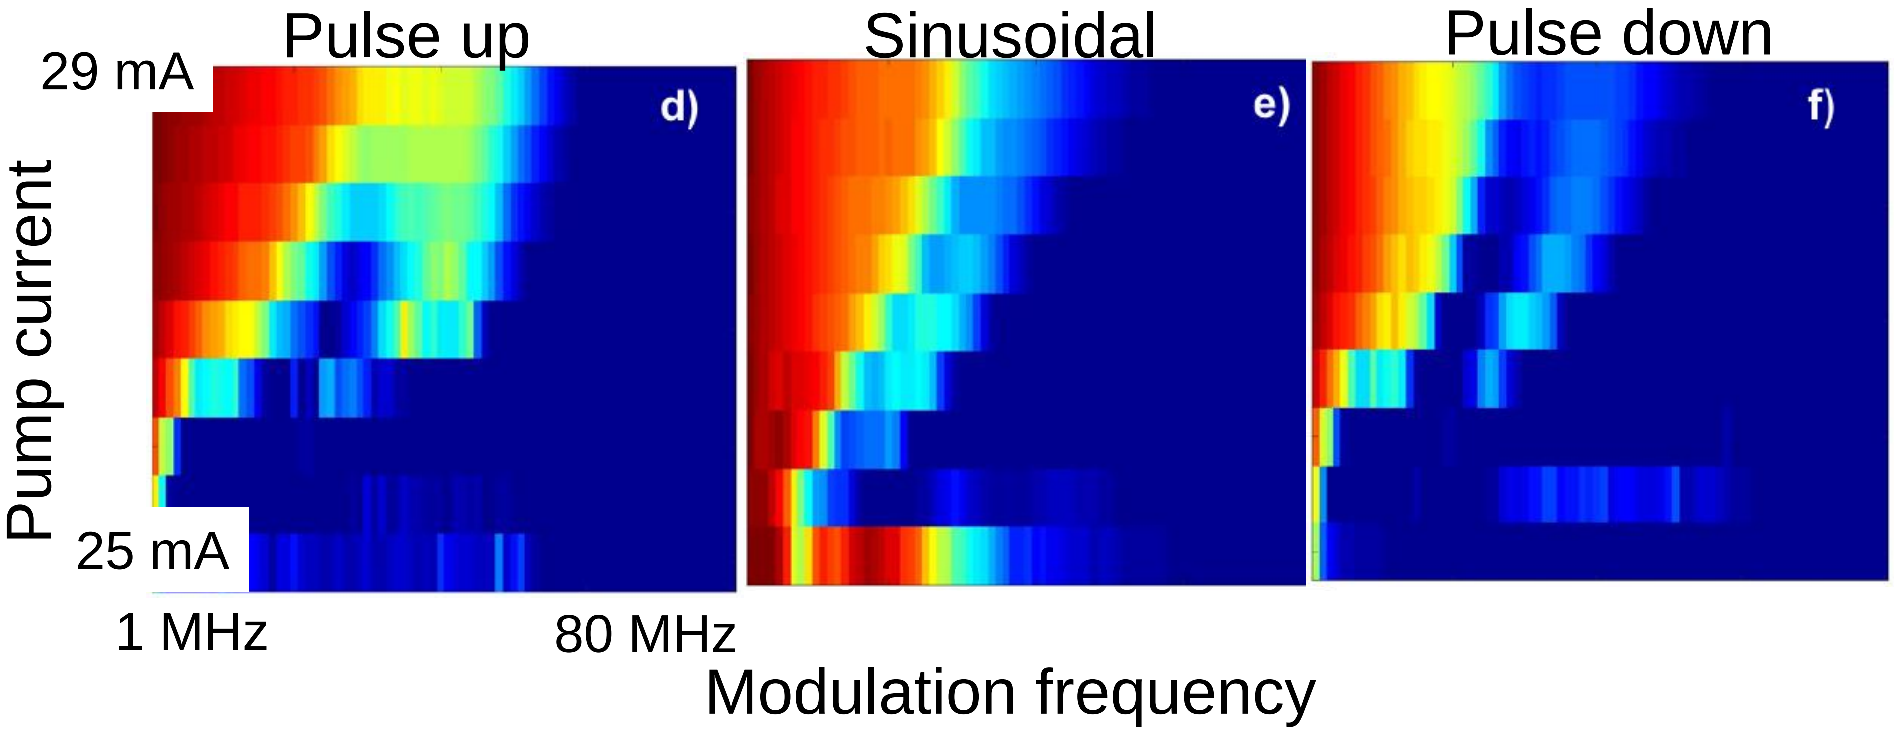
Waveform comparison: in color code the success rate (red SR=1)



⇒ pulse-down waveform produces a wider locking region

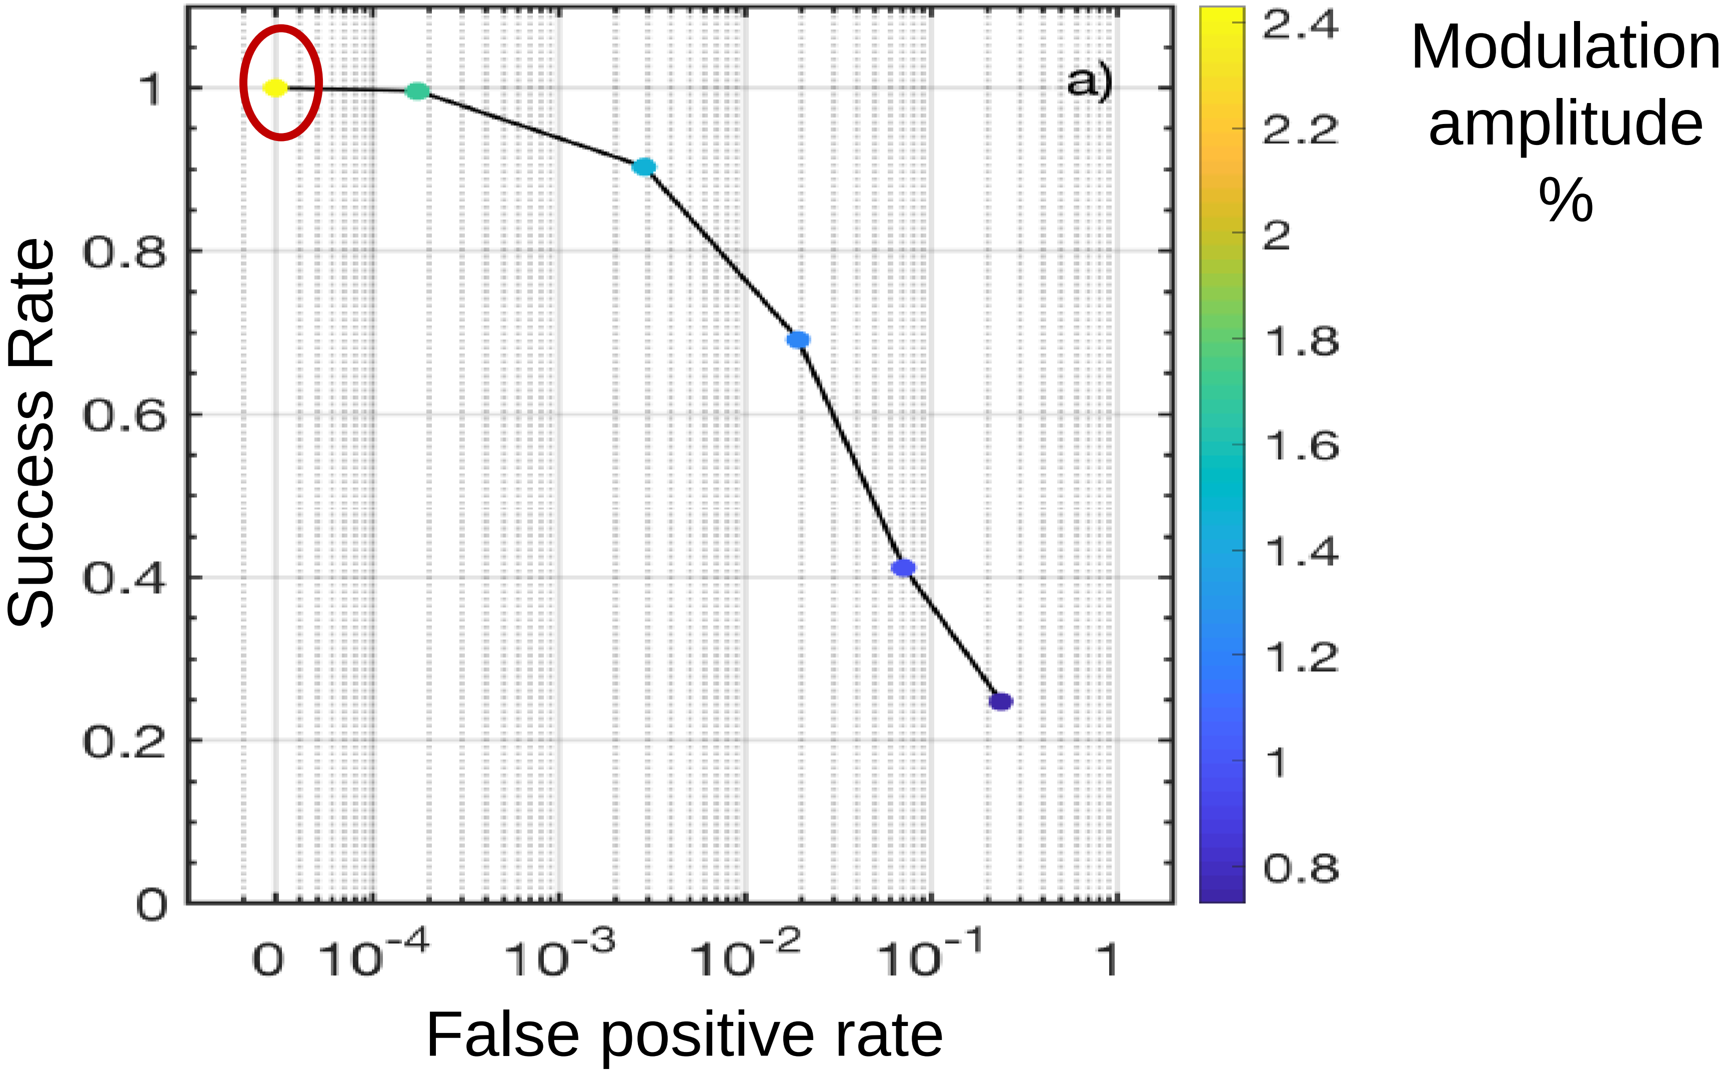
J. Tiana et al., Opt. Express 26 9298 (2018)

And the false positives? (the natural, uncontrolled spikes)



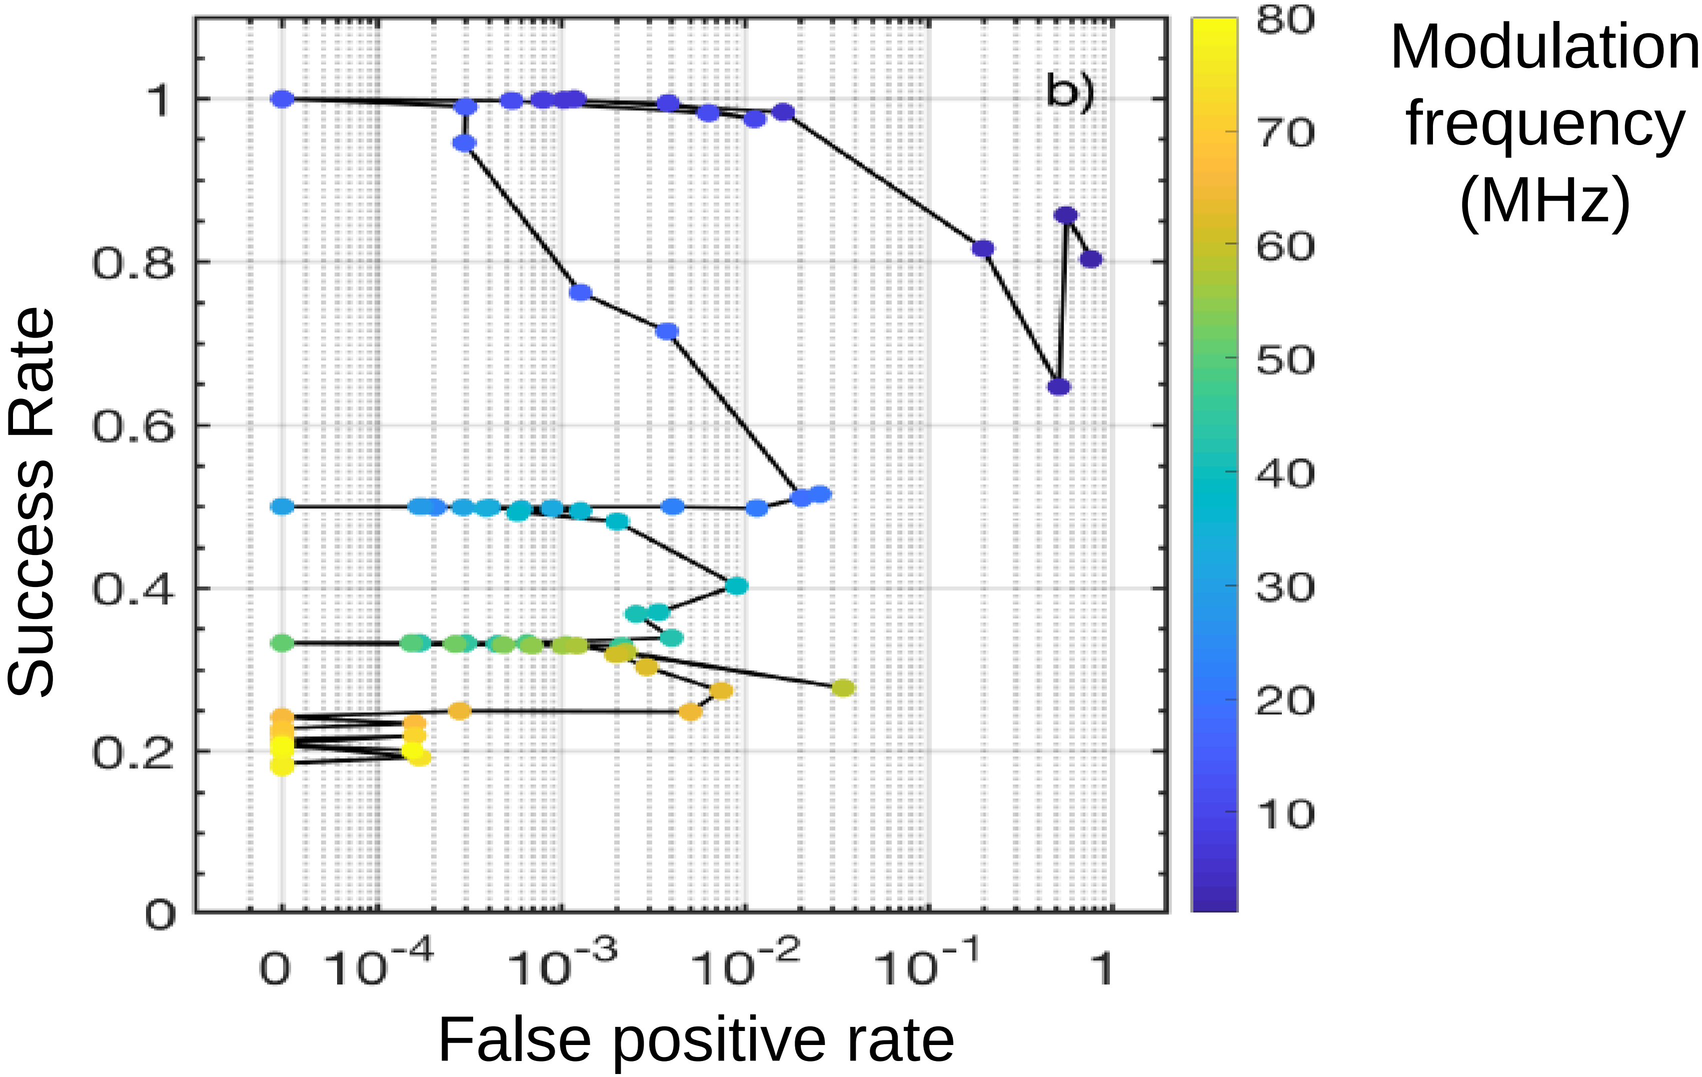
J. Tiana et al., Opt. Express 26, 9298 (2018)

Receiver operating characteristic (ROC) curves



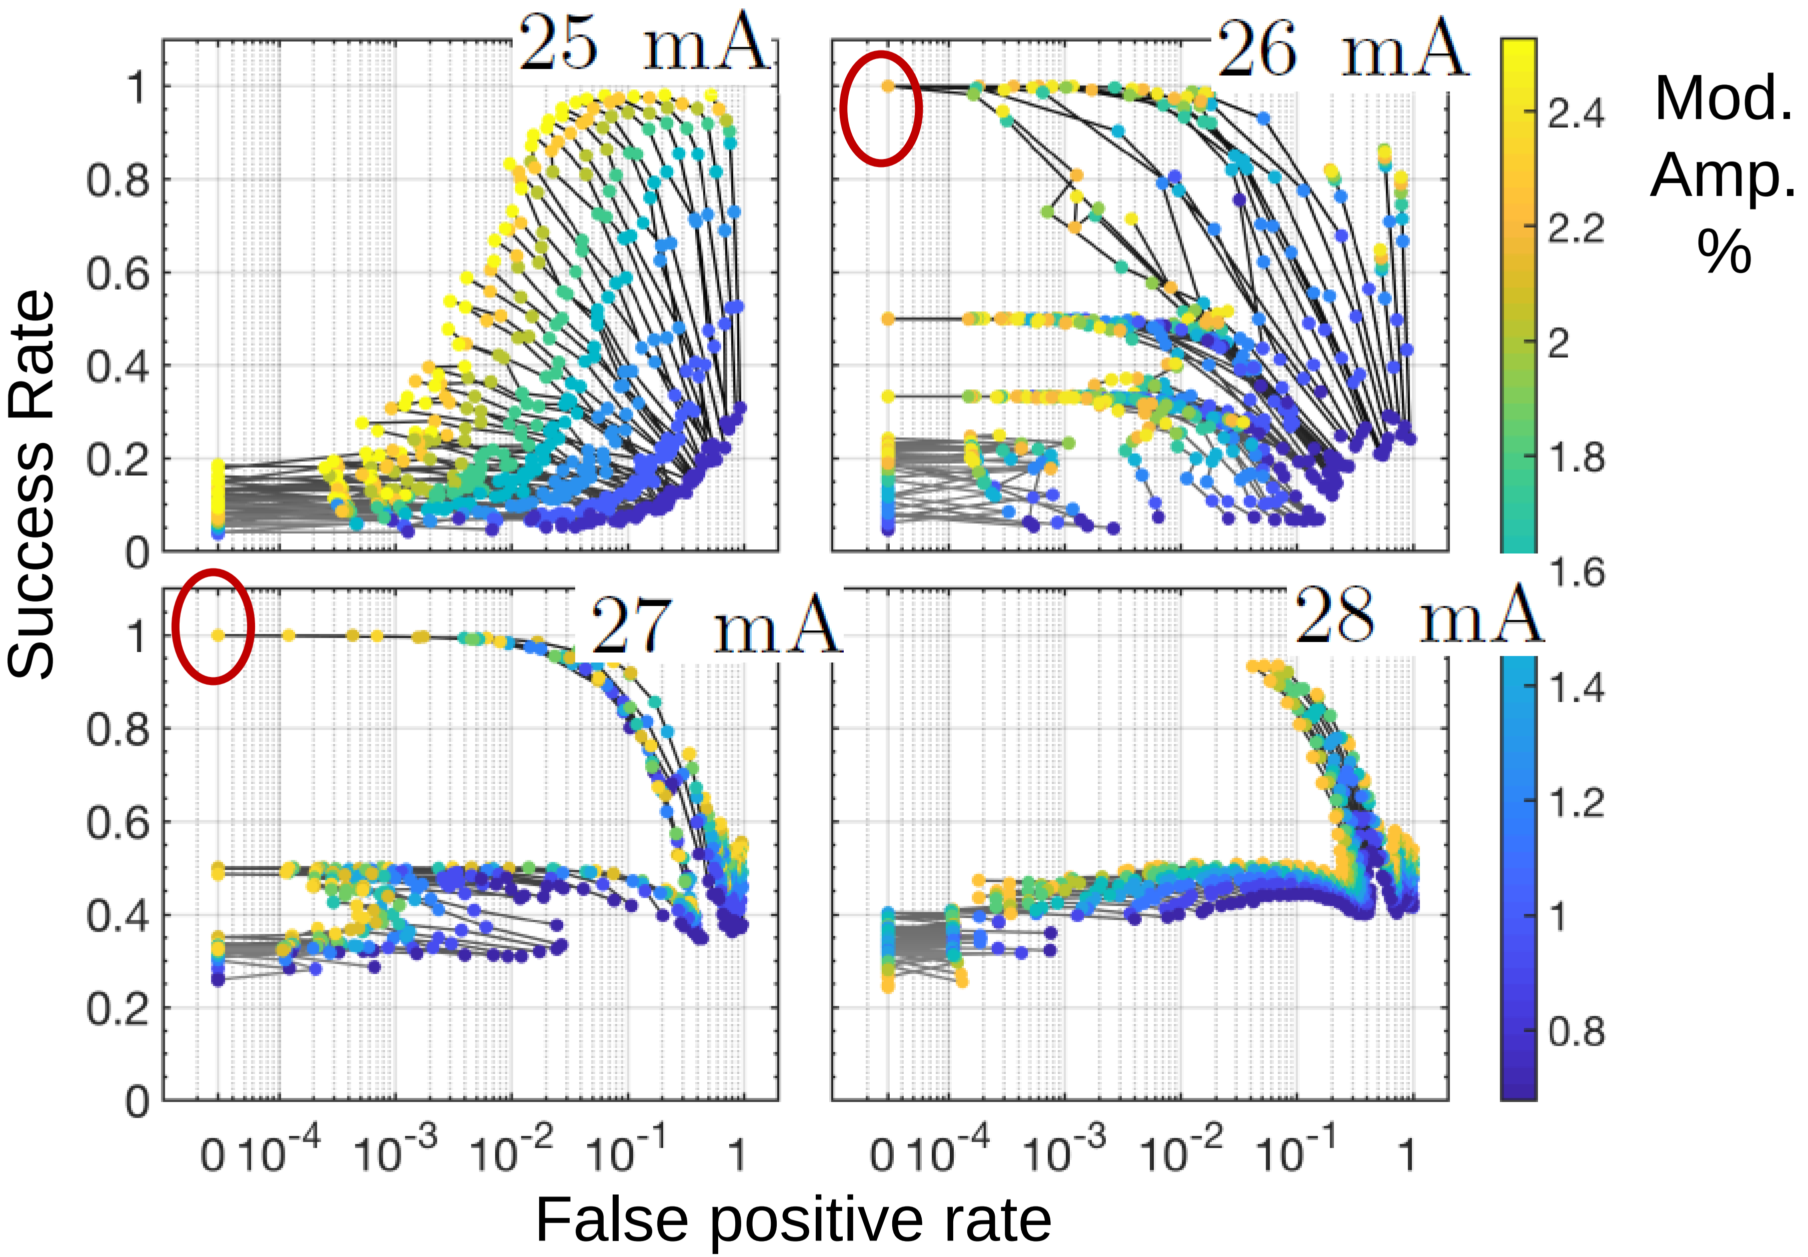
J. Tiana et al., arXiv:1806.08950v1 (2018)

Locked-unlocked transitions when the modulation frequency increases



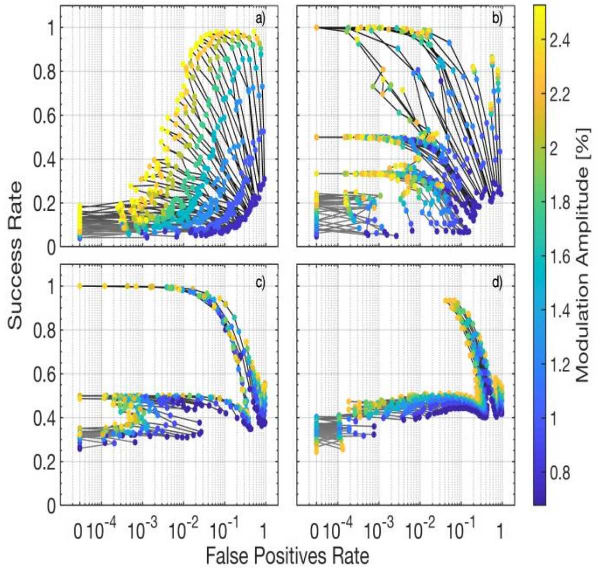
J. Tiana et al., arXiv:1806.08950v1 (2018)

Role of the laser current (controls the natural spike rate)

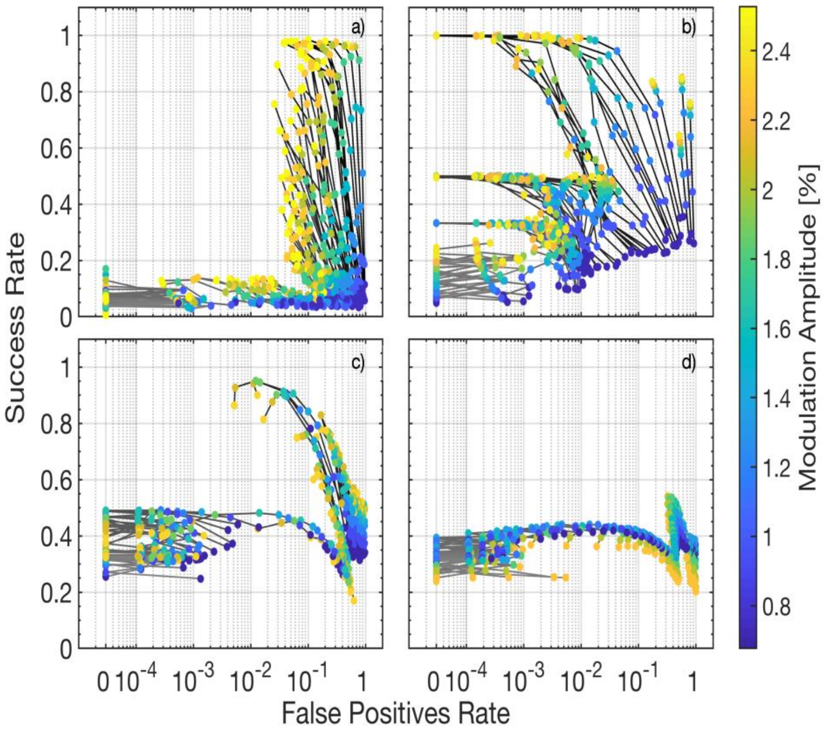


Influence of the modulation waveform

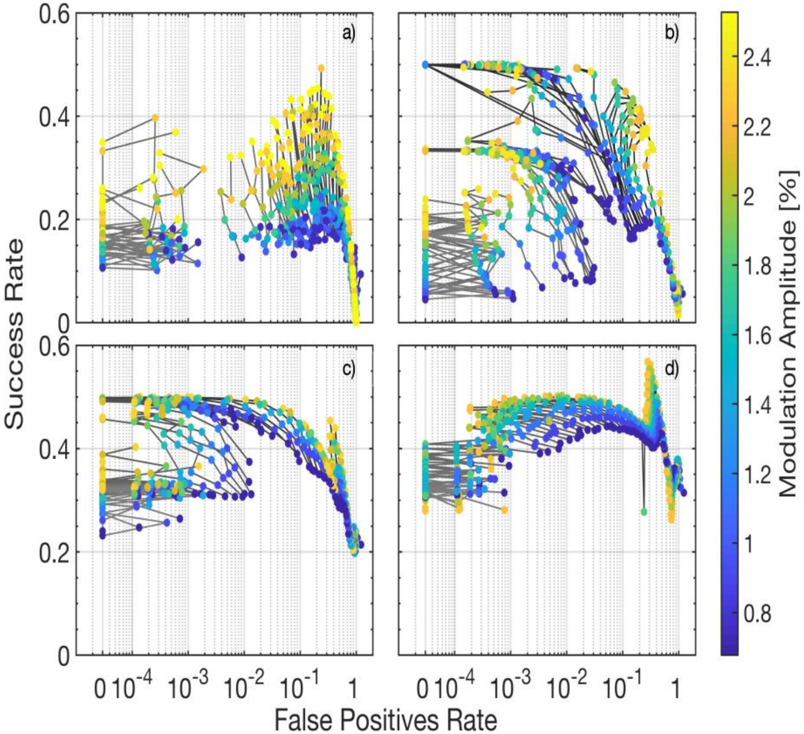
Pulsed-down



Pulsed-up



Sinusoidal



What did we learn?

- Transition to optical chaos: ordinal analysis distinguishes different regimes.
- Spike patterns that are more/less expressed are not always detected by correlation analysis.
- Minimal model identified (a modified circle map).
- Good agreement between optical & neuron (synthetic) spikes.
- ROC curves allow to quantify the entrainment quality.
- Regions of perfect 1:1 locking identified.

Ongoing work: potential for sensing applications?

To do in the future: The connection with the circle map needs to be explored.
